# Siam Suits Platform Upgrade

2026-09-19

## Why We Rebuilt the Platform

The original Siam Suits system was built early on, one feature at a time, without a plan for growing beyond a single business. As the business has grown, four gaps kept showing up in the old system. The new platform closes all four of them.

| | Old System | New System |
|---|---|---|
| **Products** | Only two fixed bundles — Suit and Tuxedo — hardcoded into the code. Adding a new bundle needed a developer. | Any combination of garments can be bundled into a sellable product from an admin screen — no code changes, ever. |
| **Staff access** | Permissions only hid menu items — a page was still reachable if you knew the URL. | Real access control: every action is checked on the server, not just hidden in a menu. |
| **Tailors** | Tailors had no login. An admin manually handed out and tracked every job by hand. | Tailors log in themselves and see only the jobs they're certified for — and claim them directly. |
| **Business scope** | The system only ever supported one business. | The platform now supports multiple independent businesses (tenants), each with its own fully separate products, retailers, tailors, and orders. |

The four sections below go through each of these in more detail, with space for real screenshots from the live app.

## 1. Dynamic Super Products

**What changed.** In the old system, "Suit" and "Tuxedo" were the only sellable bundles, and the logic that combined a Jacket + Pant into a "Suit" was hardcoded directly into the code. Wanting to sell a Vest, an Overcoat, or any new combination meant a developer had to write and ship new code.

**What's new.** Any admin can now define a "Super Product" — any combination of underlying garments/components — entirely from an admin screen. A "Three-Piece Suit" can be built from Jacket + Pant + Vest, or a "Shirt" can stand alone as a one-component product. Each component keeps its own measurements, styling options, and manufacturing steps, and the bundle itself is just data, not code.

**Why it matters.** New product lines can launch the same day they're decided on, with no engineering time and no risk of breaking existing orders.

*Screenshot needed: the Super Products admin screen showing the component builder (e.g. adding Jacket + Pant + Vest to a super product).*

## 2. Full Role-Based Access Control (RBAC)

**What changed.** The old system's "permissions" only hid menu items in the sidebar. The underlying pages and API endpoints had no real protection — anyone who knew or guessed a URL could still open or use a page they weren't supposed to see.

**What's new.** Every role and permission is now defined by an admin, and every single action — not just what's visible in the menu — is checked against the logged-in user's real permissions on the server itself. Roles can be created freely (e.g. "Order Manager," "Catalog Editor," "Payroll Admin"), each with its own precise set of permissions, and assigned to any number of staff.

**Why it matters.** Access control is now real security, not cosmetic — and new roles can be created for new hires without any code changes.

*Screenshot needed: the Roles admin screen showing the permission checkbox editor for a role.*

## 3. Tailor Self-Service Module

**What changed.** Tailors had no login of their own. All job assignment was done manually by an admin, tracking who was doing what by hand — slow, error-prone, and with no visibility for the tailor into their own workload.

**What's new.** Every tailor now has their own login. Once logged in, a tailor sees a live job board of available jobs — but only the ones matching the processes/skills they're certified for. A tailor can claim (self-assign) a job directly and mark it complete when done, and the system tracks it automatically for payroll.

**Why it matters.** Tailors get full visibility into their own work queue, admins no longer manually push out every job by hand, and payroll is calculated from real, verified job completions rather than a spreadsheet.

*Screenshots needed: (1) the tailor login screen, and (2) a tailor's job board showing available and assigned jobs.*

## 4. Multi-Tenant Platform

**What changed.** The old system was built for exactly one business. There was no concept of separating data between different companies — running a second business on it would have meant standing up a second, entirely separate deployment.

**What's new.** The platform is now multi-tenant. Each business (tenant) that signs up gets its own fully isolated universe — its own super products, products, retailers, tailors, staff, and orders — completely invisible to every other tenant. New businesses can be onboarded from a platform admin panel without touching any code or infrastructure.

**Why it matters.** Siam Suits can now be offered as a product to other businesses, not just used internally — this is what turns it into a real SaaS platform.

## Screenshots Needed to Finish This Document

Send over the following and I'll drop each one straight into the matching section above.

1. **Super Products admin — component builder.** The Super Products admin page, open on the builder for a super product showing components being added.
2. **Roles admin — permission editor.** The Roles admin page, open on a role's edit view showing the permission checkboxes.
3. **Tailor login screen.** The tailor-facing login page.
4. **Tailor job board.** A logged-in tailor's view of available/assigned jobs.
5. **Platform admin — tenant list.** The platform superadmin panel showing the list of tenants (or the create/onboard-tenant form).

Optional, but nice to have:

6. Order builder showing a multi-component super product being ordered end-to-end.
7. A completed order's manufacturing/job-tracking view.
